One of the starting points of Probability was the classical random walk where

$X_k = \pm 1$ with Prob. p and $1 - p$ resp. for $k \geq 1$ (with $p \in (0, 1)$) are independent random variables

Their partial sums are denoted by $S_n = \sum_{k=1}^n X_k$ for $n \geq 1$.

The classical limit theorems where proven

WLN & SLN

$$\frac{S_n}{n} \rightarrow E(X_1) = 2p - 1 \quad \text{as } n \rightarrow \infty \quad \text{in Prob. or a.s.}$$

CLT

$$\frac{S_n - n(2p - 1)}{\sqrt{n}} \xrightarrow{d} \mathcal{N}_{0, 4p(1-p)} \quad \text{as } n \rightarrow \infty.$$

LIL

$$\limsup_{n \rightarrow \infty} (\liminf_{n \rightarrow \infty}) \frac{S_n - n(2p - 1)}{\sqrt{8p(2p - 1)n \log \log n}} \stackrel{a.s.}{=} 1(-1).$$

Furthermore Invariance Principles, Level Crossings etc.

There are many different models to generalize the simple situation of an ordinary random walk, e.g.:

- i) Random walks in a random environment (RWRE)
- ii) Random walks with certain dependence structures:
e.g., The Elephant Random Walk (ERW)

An elephant is known to have a long memory, so for an ERW the step at time n depends on the whole past.

Belongs to the family of reinforced random processes.

There are many different models to generalize the simple situation of an ordinary random walk, e.g.:

- i) Random walks in a random environment (RWRE)
- ii) Random walks with certain dependence structures:
e.g., The Elephant Random Walk (ERW)

An elephant is known to have a long memory, so for an ERW the step at time n depends on the whole past.

Belongs to the family of reinforced random processes.

For the elephant random walk $X_1 \sim 2\mathcal{B}_{1,p} - 1$, ($p \in (0, 1)$) as before and then for $n \geq 1$ inductively

$$X_{n+1} = \begin{cases} +X_K, & \text{with probability } p, \\ -X_K, & \text{with probability } 1 - p, \end{cases}$$

where K is again a random variable being uniformly distributed on $\{1, \dots, n\}$ and being independent of $\mathcal{G}_n = \sigma(X_1, \dots, X_n)$.

S_n denote the partial sums again.

Rem.:

0)

Name, because the memory of an Elephant is known to be long ranging.

i) Not a Markovian process.

ii) Can as well be formulated as an urn model

iii)

$$E(X_{n+1} | \mathcal{G}_n) = \frac{1}{n} \left(p \sum_{k=1}^n X_k + (1-p) \sum_{k=1}^n (-X_k) \right) = (2p-1) \frac{S_n}{n}$$

and hence we get

- 0. Introduction of myself
 - 1. The classical random walk
 - The ERW with basic results**
 - 2. Variations of the memory
 - 3. Zeros - and level crossings
 - 4. Random walks with stops
- Some Literature, related to the talk

$$E(S_{n+1} | \mathcal{G}_n) = S_n + E(X_{n+1} | \mathcal{G}_n) = \frac{n + 2p - 1}{n} S_n =: \gamma_n S_n.$$

Then with

$$a_n = \prod_{k=1}^{n-1} \gamma_k^{-1} = \frac{\Gamma(2p) \cdot \Gamma(n)}{\Gamma(n + 2p - 1)}, \quad n \geq 1,$$

we find that $(M_n) = (a_n S_n)$ is a martingale.

(Coletti et al. (2017), Bercu (2018), see also C. Heyde (2004))

and we can use martingale theory.

Note that $a_n \sim \Gamma(2p) n^{2p-1}$, $n \rightarrow \infty$.

- 0. Introduction of myself
 - 1. The classical random walk
 - The ERW with basic results**
 - 2. Variations of the memory
 - 3. Zeros - and level crossings
 - 4. Random walks with stops
- Some Literature, related to the talk

$$E(S_{n+1} | \mathcal{G}_n) = S_n + E(X_{n+1} | \mathcal{G}_n) = \frac{n + 2p - 1}{n} S_n =: \gamma_n S_n.$$

Then with

$$a_n = \prod_{k=1}^{n-1} \gamma_k^{-1} = \frac{\Gamma(2p) \cdot \Gamma(n)}{\Gamma(n + 2p - 1)}, \quad n \geq 1,$$

we find that $(M_n) = (a_n S_n)$ is a martingale.

(Coletti et al. (2017), Bercu (2018), see also C. Heyde (2004))

and we can use martingale theory.

Note that $a_n \sim \Gamma(2p) n^{2p-1}$, $n \rightarrow \infty$.

We may write

$$M_n = \sum_{k=1}^n a_k \varepsilon_k \text{ with } \varepsilon_k = (S_k - \gamma_{k-1} S_{k-1})$$

and we find

$$E(\varepsilon_{n+1}^2 | \mathcal{G}_n) = 1 - (2p - 1)^2 (S_n/n)^2 \leq 1$$

implying $\langle M_n \rangle = \sum_{k=1}^n a_k^2 E(\varepsilon_k^2 | \mathcal{G}_{k-1}) \approx \sum_{k=1}^n a_k^2$.

For the asymptotic behavior of (M_n) the quantity $\nu_n = \sum_{k=1}^n a_k^2$ is essential and

$$\nu_n \begin{cases} \sim (\Gamma(2p))^2 \frac{n^{1-2(2p-1)}}{3-4p}, & \text{for } p < 3/4 \\ \sim \frac{\pi}{4} \log n, & \text{for } p = 3/4 \\ \rightarrow C, & \text{for } p > 3/4 \end{cases}$$

one obtains by well-known results for martingales for M_n and then for S_n

Theorem (Bercu (2018))

(a) For $p < 3/4$ (diffusive scheme),

$$\frac{S_n}{n} \xrightarrow{\text{a.s.}} 0 \quad \text{and} \quad \frac{S_n}{\sqrt{n}} \xrightarrow{d} \mathcal{N}_{0, \frac{1}{3-4p}}, \quad \text{as } n \rightarrow \infty.$$

(b) For $p = 3/4$ (critical scheme),

$$\frac{S_n}{\sqrt{n \log n}} \xrightarrow{\text{a.s.}} 0 \quad \text{and} \quad \frac{S_n}{\sqrt{n \log n}} \xrightarrow{d} \mathcal{N}_{0,1}, \quad \text{as } n \rightarrow \infty.$$

(c) For $p > 3/4$ (superdiffusive scheme),

$$\frac{S_n}{n^{2p-1}} \xrightarrow{\text{a.s.}} L, \quad \text{as } n \rightarrow \infty,$$

where L is a non-degenerate random variable.

There were simulation papers dealing with partial memory of the elephant. People in Physics asked **what happens for different memories? When is there such a dichotomy?**

We now deal with a partial memory of the elephant described by $\mathcal{F}_n = \sigma(X_j, j \in I_n)$ for some memory subset $I_n \subset \{1, \dots, n\}$ of the elephant. Then,

$$\begin{aligned} E(X_{n+1} | \mathcal{F}_n) &= p \cdot \sum_{i \in I_n} \frac{1}{|I_n|} X_i + (1-p) \cdot \sum_{i \in I_n} \frac{1}{|I_n|} (-X_i) \\ &= (2p-1) \cdot \frac{\sum_{i \in I_n} X_i}{|I_n|}, \end{aligned}$$

Remember: I_n is the set of indices describing the memory

Now, assume $m \in \mathbb{N}$ is fixed and

$$I_n = \{1, \dots, n\} \text{ for } n = 1, \dots, m \text{ and } I_n = \{1, \dots, m\} \text{ for } m < n$$

The process (S_n) has neither a martingale nor a Markovian structure, but one can prove the following (here $m = 2$).

Theorem

1a) As $n \rightarrow \infty$

$$(a) \quad \frac{S_n}{n} \xrightarrow{d} \begin{cases} 2p - 1, & \text{with probability } p^2, \\ 0, & \text{with probability } 1 - p, \\ -(2p - 1), & \text{with probability } p(1 - p), \end{cases};$$

$$(b) \quad E(S_n/n) \rightarrow p(2p - 1)^2 \text{ and}$$

$$\text{Var}(S_n/n) \rightarrow p(1 - p)(2p - 1)^2(4p^2 + 1).$$

- 0. Introduction of myself

- 2.a Remembering only the distant past**
- 2.b Remembering only the recent past
- 2.c Remembering only the first and last past

For general $m \in \mathbb{N}$

Theorem

1c) Let $q_k = P(S_m = m - 2k)$, $r_k = ((m - k)p + k(1 - p))/m$, and $p_k = (m - 2k)(2p - 1)/m$, where $0 \leq k \leq m$ and $m \in \mathbb{N}$, then

$$\frac{S_n}{n} \xrightarrow{d} \sum_{k=0}^m q_k \delta_{p_k} \text{ as } n \rightarrow \infty,$$

and

$$\frac{S_n - n(2p - 1)S_m/m}{\sqrt{n}} \xrightarrow{d} \sum_{k=0}^m q_k \mathcal{N}_{0, 4r_k(1-r_k)} \quad n \rightarrow \infty.$$

Question: What about $m = m_n \rightarrow \infty$ s.t. $m_n/n \rightarrow 0$?

- 0. Introduction of myself
 - 1. The classical random walk
 - The ERW with basic results
 - 2. Variations of the memory
 - 3. Zeros - and level crossings
 - 4. Random walks with stops
- Some Literature, related to the talk

- 2.a Remembering only the distant past
- 2.b Remembering only the recent past
- 2.c Remembering only the first and last past

For general $m \in \mathbb{N}$

Theorem

1c) Let $q_k = P(S_m = m - 2k)$, $r_k = ((m - k)p + k(1 - p))/m$, and $p_k = (m - 2k)(2p - 1)/m$, where $0 \leq k \leq m$ and $m \in \mathbb{N}$, then

$$\frac{S_n}{n} \xrightarrow{d} \sum_{k=0}^m q_k \delta_{p_k} \text{ as } n \rightarrow \infty,$$

and

$$\frac{S_n - n(2p - 1)S_m/m}{\sqrt{n}} \xrightarrow{d} \sum_{k=0}^m q_k \mathcal{N}_{0, 4r_k(1-r_k)} \quad n \rightarrow \infty.$$

Question: What about $m = m_n \rightarrow \infty$ s.t. $m_n/n \rightarrow 0$?

Theorem

(a) If $0 < p < 3/4$, then

$$\frac{S_n \sqrt{m_n}}{n} \xrightarrow{d} \mathcal{N}_{0, (2p-1)^2 / (3-4p)}, \text{ as } n \rightarrow \infty.$$

(b) If $p = 3/4$, then

$$\frac{S_n \sqrt{m_n / \log m_n}}{n} \xrightarrow{d} \mathcal{N}_{0, 1/4}, \text{ as } n \rightarrow \infty.$$

(c) If $3/4 < p < 1$, then

$$\frac{S_n m_n^{2(1-p)}}{n} \xrightarrow{d} (2p-1)L, \text{ as } n \rightarrow \infty,$$

where the random variable L is the same as in Theorem above.

- 0. Introduction of myself

For the case of nonuniform distribution of K , see Laulin (2022), Majumdar & Maulik (2025).

E.g., Laulin uses $P(K = k) = \frac{\Gamma(n+\beta)}{\Gamma(n)\Gamma(\beta)}$ with $\beta \geq 0$ and shows among other results in the diffusive case $p < \frac{4\beta+3}{4(\beta+1)}$

$$\frac{S_n}{\sqrt{n}} \xrightarrow{d} \mathcal{N}_{0, \sigma_\beta^2} \text{ as } n \rightarrow \infty$$

where $\sigma_\beta^2 = \frac{\beta+1-p}{(1-p)(1+2\beta-2(2p-1)(\beta+1))}$.

The larger the memory, the more tedious are calculations of e.g., moments, typically one can use difference equations, as in the most simple case. Let be given $X_1 = 1$

$$\begin{aligned}
 E(X_{n+1}) &= E(E(X_{n+1} | \sigma\{X_1, X_n\})) = (2p - 1) \left(\frac{E(X_1) + E(X_n)}{2} \right) \\
 &= \frac{(2p - 1)}{2} (E(X_n) + 1) \quad \text{and thus} \\
 E(X_n) &= \frac{2p - 1}{3 - 2p} + (p - 1/2)^{n-1} \frac{4(1 - p)}{3 - 2p}
 \end{aligned}$$

and

$$E(S_n) = n \cdot \frac{2p - 1}{3 - 2p} + \frac{8(1 - p)}{(3 - 2p)^2} + o(1).$$

etc . for higher moments

The order of the difference equations increase with moments and the size of the memory.

The basis for the proof is a Brownian embedding:

Notations

$M_k(n) = a_{n+k} S_{n+k}$ is a binary splitting martingale given $S_k = 0$

Then one can construct an increasing sequence $(T_{k,n}), n \geq 1$ such that for fixed k

the sequences $(M_k(n))$ and $(B(T_{k,n}))$ have the same law.

Finally we can relate the zeros as

$$\{n \geq 0 : M_k(n) = 0\} = \{n \geq 0 : B(T_{k,n} = 0)\}.$$

Consider possible asymptotics for the first passage times

$$\tau_n = \min\{k \in \mathbb{N} : S_k \geq n\} = \min\{k : S_k = n\}, \quad n \geq 1.$$

A first observation is that the stopping times are not proper random variables in the superdiffusive case.

Consider possible asymptotics for the first passage times

$$\tau_n = \min\{k \in \mathbb{N} : S_k \geq n\} = \min\{k : S_k = n\}, \quad n \geq 1.$$

A first observation is that the stopping times are not proper random variables in the superdiffusive case.

If τ_n would be finite a.s. for a subsequence $n_k \nearrow \infty$, then, as $\tau_{n_k} \nearrow \infty$,

$$\frac{S_{\tau_{n_k}}}{\tau_{n_k}^{2p-1}} = \frac{n_k}{\tau_{n_k}^{2p-1}} \xrightarrow{\text{a.s.}} L \text{ as } k \rightarrow \infty.$$

However, since $E(S_n/n^{2p-1} | X_1 = -1) \sim -\frac{2p}{\Gamma(2p)}$ as $n \rightarrow \infty$, L cannot be a positive random variable, thus yielding a contradiction. Hence, $\tau_{n_k} = \infty$ for all $k \geq k_0$ on a set of positive measure, which implies that $\tau_n = \infty$ for all $n \geq k_0$ there.

Consider possible asymptotics for the first passage times

$$\tau_n = \min\{k \in \mathbb{N} : S_k \geq n\} = \min\{k : S_k = n\}, \quad n \geq 1.$$

A first observation is that the stopping times are not proper random variables in the superdiffusive case.

If τ_n would be finite a.s. for a subsequence $n_k \nearrow \infty$, then, as $\tau_{n_k} \nearrow \infty$,

$$\frac{S_{\tau_{n_k}}}{\tau_{n_k}^{2p-1}} = \frac{n_k}{\tau_{n_k}^{2p-1}} \xrightarrow{\text{a.s.}} L \text{ as } k \rightarrow \infty.$$

However, since $E(S_n/n^{2p-1} | X_1 = -1) \sim -\frac{2p}{\Gamma(2p)}$ as $n \rightarrow \infty$, L cannot be a positive random variable, thus yielding a contradiction. Hence, $\tau_{n_k} = \infty$ for all $k \geq k_0$ on a set of positive measure, which implies that $\tau_n = \infty$ for all $n \geq k_0$ there.

In the diffusive case we obtain strong laws and almost sure bounds.

Theorem

$$(i) \text{ For } 0 < p < 3/4, \quad \liminf_{n \rightarrow \infty} \frac{\tau_n \log \log n}{n^2} \geq \frac{3 - 4p}{2} \text{ a.s.}$$

$$(ii) \text{ For } p = 3/4, \quad \liminf_{n \rightarrow \infty} \frac{\tau_n \log n \log \log \log n}{n^2} \geq \frac{1}{2} \text{ a.s.}$$

Rem.:

(i) For $0 < p \leq 3/4$ it follows, in particular, that $\frac{\tau_n}{n} \xrightarrow{a.s.} \infty$ and, hence, that $\frac{E(\tau_n)}{n} \rightarrow \infty$ as $n \rightarrow \infty$. This might be interpreted as a negative renewal theorem, in that the almost sure limit equals $1/\mu < \infty$ for random walks with positive mean μ .

(ii) For $3/4 < p < 1$ the LLN for S_n does not imply an LLN for τ_n . However, for

$\tau_n^* = \min\{k : |S_k| = n\}$ we have

$$\frac{\tau_n^*}{n^{1/(2p-1)}} \xrightarrow{a.s.} |L|^{-1/(2p-1)} n \rightarrow \infty.$$

Rem.:

(i) For $0 < p \leq 3/4$ it follows, in particular, that $\frac{\tau_n}{n} \xrightarrow{a.s.} \infty$ and, hence, that $\frac{E(\tau_n)}{n} \rightarrow \infty$ as $n \rightarrow \infty$. This might be interpreted as a negative renewal theorem, in that the almost sure limit equals $1/\mu < \infty$ for random walks with positive mean μ .

Distributional convergence

Theorem

(i) For $0 < p < 3/4$, $P\left(\frac{\tau_n}{n^2} \leq x\right) \xrightarrow{d} G_p(x)$ as $n \rightarrow \infty$, where

$$\begin{aligned} G_p(x) &= P\left(\frac{1}{\sqrt{3-4p}} \max_{0 < t \leq x} \{t^{2p-1} W(t^{3-4p})\} \geq 1\right) \\ &= P\left(\max_{0 < t \leq 1} \left\{t^{(2p-1)/(3-4p)} W(t)\right\} \geq \sqrt{\frac{3-4p}{x}}\right). \end{aligned}$$

(ii) For $p = 3/4$,

$P\left(\frac{\tau_n \log n}{n^2} \leq x\right) \xrightarrow{d} 2\left(1 - \mathcal{N}_{0,1}(1/\sqrt{x})\right)$ as $n \rightarrow \infty$.

- 0. Introduction of myself

Rem.: $E(\tau_n) = \infty$ for $p \in [1/4, 3/4)$.

What about different memories, e.g., $l_n = \{n\}$

Theorem

Here we have

$$\frac{p \tau_n}{(1-p)n^2} \xrightarrow{d} S(1/2, 1/2) \quad n \rightarrow \infty$$

where $S(1/2, 1/2)$ is the distribution of $1/\chi_1^2$.

- 0. Introduction of myself
 - 1. The classical random walk
The ERW with basic results
 - 2. Variations of the memory
 - 3. Zeros - and level crossings
 - 4. Random walks with stops
- Some Literature, related to the talk

Rem.: $E(\tau_n) = \infty$ for $p \in [1/4, 3/4)$.

What about different memories, e.g., $l_n = \{n\}$

Theorem

Here we have

$$\frac{p\tau_n}{(1-p)n^2} \xrightarrow{d} S(1/2, 1/2) \quad n \rightarrow \infty$$

where $S(1/2, 1/2)$ is the distribution of $1/\chi_1^2$.

Now stops are permitted, that is, we assume that our basic random variable follows

$$X_1 = \begin{cases} +1, & \text{with probability } p, \\ -1, & \text{with probability } q, \\ 0, & \text{with probability } r = 1 - p - q \end{cases}$$

and

$$X_{n+1} = \begin{cases} +X_K, & \text{with probability } p, \\ -X_K, & \text{with probability } q \\ 0, & \text{with probability } r = 1 - p - q \end{cases}$$

That means the random walk stops from time to time and then goes on but with a slightly different dynamic.

- 0. Introduction of myself

Then we may ask: How many zeros do occur, i.e.,
 $N_n = \sum_{k=1}^n \mathbb{1}_{\{X_k=0\}} = ?$ or $N_n^* = n - N_n = ?$

Theorem

Here we have

$$\frac{N_n^*}{n^{1-r}} = \frac{n - N_n}{n^{1-r}} \xrightarrow{\text{a.s.}} Y$$

with some positive random variable Y having moments

$$E(Y) = \frac{1}{\Gamma(1-r)} \quad \text{and} \quad \text{Var}(Y) = d_r - \frac{1}{\Gamma^2(1-r)}.$$

Rem.: Related results we obtain for different memories.

- 0. Introduction of myself

The ERW with basic results
 - 2. Variations of the memory
 - 3. Zeros - and level crossings
 - 4. **Random walks with stops**
- Some Literature, related to the talk

Now, the limit distributions for S_n are quite different.

We have to normalize by the number of the nonzero contributions in the walk: N_n^*

For that we can consider a so-called Bernoulli ERW $T_n = \sum^n Y_k$, where with K as before

$$Y_{n+1} = \begin{cases} +Y_K, & \text{with probability } 1 - r, \\ 0, & \text{with probability } r, \end{cases}$$

Now we need to define the Mittag-Leffler distributions ML_α which for $0 < \alpha < 1$ is the distribution with moment generating function $M_\alpha(t) = \sum_{n=0}^{\infty} t^n / \Gamma(1 + n\alpha)$

- 0. Introduction of myself
 - 1. The classical random walk

Theorem

For $0 < r < 1$ we have as $n \rightarrow \infty$

$$P\left(\frac{T_n}{n^{1-r}} \leq x\right) \rightarrow (1-r)ML_{1-r}(x) + r\delta_0(x).$$

We can also deal with different memories, e.g., $I_n = \{1, n\}$ then

Theorem

As $n \rightarrow \infty$ we have for $x \in \mathbb{R}$

$$P\left(\frac{S_n - \frac{np}{2-p} \mathbb{I}\{X_1 = 1\}}{\sqrt{n}} \leq x\right) \rightarrow p\mathcal{N}_{0, \sigma(p)^2}(x) + (1-p)\delta_0(x).$$

- 0. Introduction of myself

Outline

0. Introduction of myself

1. The classical random walk

The ERW with basic results

2. Variations of the memory

3. Zeros - and level crossings

4. Random walks with stops

Some Literature, related to the talk
